ARRANGEMENT FOR OPTIMIZING THE DATA TRANSMISSION OVER A BIDIRECTIONAL

RADIO CHANNEL

PRELIMINARY AMENDMENT

BOX PATENT APPLICATION

Assistant Commissioner for Patents Washington, DC 20231

August 25, 2000

Sir:

The following Preliminary Amendments and Remarks respectfully submitted in connection with the above-identified application.

AMENDMENTS

IN THE SPECIFICATION:

Please amend the specification as follows:

Before line 1, insert -- This application is the national phase under 35 U.S.C. § 371 of PCT International Application No. PCT/EP99/01220 which has an International filing date of February 25, 1999, which designated the United States of America. --

IN THE ABSTRACT:

Please add the Abstract as follows:

-- The invention relates to an arrangement for optimizing the data transmission over a bidirectional radio channel. According to the invention, the digital data to be transmitted according to

ſП r Lj T. į.

a data transmission protocol is divided into individual data packets in each of two transmitting/receiving stations. In each transmitting/receiving station, the number and/or priority and/or type (e.g. information, control characters, repeat blocks) of the data packets generate by the data transmission protocol of the higher level and transmitted to the respective transmitter of the station is determined (data packet identifications). According to the data packet identifications, the data transmission protocol is then selected in at least one of the stations in accordance with an optical utilization of the radio channel capacity.—

IN THE CLAIMS:

Please amend the claims as follows:

Claim 2: Line 1, change "Method" to -- The method--; and

change "Claim" to --claim--

Claim 3: Line 1, change "Method" to -- The method--; and

change "Claim" to --claim--

Claim 4: Line 1, change "Method" to -- The method--; and

change "one of the preceding claims" to

--claim 1--

REMARKS

The specification has been amended to provide a cross-reference to the previously filed International Application. The claims have also been amended to delete multiple dependents and to place the application into better form for examination. Entry

TRW/cqc

4100-117P

of the present amendment and favorable action on the aboveidentified application are respectfully requested.

If necessary, the Commissioner is hereby authorized in this, concurrent, and future replies, to charge payment or credit any overpayment to Deposit Account No. 02-2448 for any additional fees required under 37 C.F.R. § 1.16 or under 37 C.F.R. § 1.17; particularly, extension of time fees.

Respectfully submitted,

Method of Optimizing the Data Transmission over a Bidirectional Radio Channel

This invention relates to and is based on a method according to the definition of the species of the main claim.

It is known that for transmission of digital data such as digitized speech or other digital information over a (bidirectional) shortwave radio channel in both transmission directions, the digital data to be transmitted, which is transmitted over the radio channel alternately in forward and reverse directions (simplex operation), can be processed according to a predetermined data transmission protocol, also referred to below as DÜP, and divided into individual data packets (e.g., according to A. S. Tanenbaum, Computer Networks, Prentice Hall, Englewood Cliffs, 1981, pages 136 ff.; European Patent No. 730,356). This digital data for transmission can also be processed first according to another data transmission protocol at a higher level, i.e., a higherlevel data transmission protocol, also referred to below as DÜPHE, e.g., according to the known TCP/IP method (transmission control protocol/Internet protocol). For optimizing data transmission over such a bidirectional radio channel, there have already been proposals to determine the bit error rate at the receiving end and transmit it back to the transmitter, where the length of the data packets is revised accordingly (older German Patent Application 196 51 593.9). Furthermore, it is also known that in a data transmission system that operates by the duplex method and has two separate transmission channels, the data rate can vary as a function of the prevailing data occurrence to make the transmission less sensitive to interference (U.S. Patent No. 5,513,213).

Depending on the type of digital data to be transmitted and the higher-level data transmission protocol (DÜPHE) processing the data, such as TCP/IP, the resulting data packets and acknowledgments in both transmission directions may vary greatly in length and frequency, and thus data throughput can be greatly impaired even when using the above-mentioned optimization

ART 34 AMDT

18-01-2000 EP 009901220

of data transmission with the data transmission protocol DÜP.

Therefore, the object of this invention is to create a method for optimizing data transmission over a bidirectional radio channel, where the available bidirectional channel capacity is optimally adapted to the data occurrence in both directions.

Starting with a method according to the definition of the species of the main claim, this object is achieved by the characterizing features of the main claim. Advantageous refinements are derived from the subordinate claims.

According to this invention, before transmitting the data packets of the data transmission protocol DÜP, data packet identifiers of the higher-level data transmission protocol DÜPHE are determined, i.e., the number and/or length and/or priority and/or type of data packets is determined, and the length of data packets of data transmission protocol DÜP is adjusted as a function thereof. A wide variety of possible combinations are conceivable for these data packet identifiers. In the simplest case, it may be sufficient to determine only the instantaneous number of data packets or the expected number of data packets. The adjustment is better if, in addition, the instantaneous or expected length of the data packets of the data to be transmitted is also taken into account as an identifier. It is even better to determine the instantaneous or expected priority of incoming data packets from the higher-level data transmission protocol DÜPHE to data transmission protocol DÜP or the instantaneous or expected type of data (information, acknowledgment, control commands or the like). Another identifier may be the respective relevance of data packets of the higher-level data transmission protocol DÜPHE, e.g., the fact that this is a repeat packet. This quantitative determination of data packet identifiers takes place on both sides of the wireless link, and then the length of data packets produced by data transmission protocol DÜP can be adjusted on the basis of these identifiers in the sense of optimum utilization of radio channel capacity, and thus also the frequency in switching between the two directions of the radio channel can be adjusted.

REVISED PAGE

WO 99/44325 PCT/EP99/01220

The figure shows a schematic diagram of a bidirectional shortwave connection between a transmitting and receiving station A and a transmitting and receiving station B. Digital data to be transmitted is divided by a higher-level data transmission protocol DÜPHE such as TCP/IP into individual data packets that are sent in succession over a radio driver RA to the data transmission protocol DÜP of the actual transmitter of station A and transmitted over the radio channel to remote station B, where the data packets are analyzed in the receiver there according to its data transmission protocol DÜP. Digital data to be transmitted is processed in the same way in the transmission operation of remote station B and sent over a radio driver RB to the data transmission protocol DÜP of the transmitter of station B and transmitted over the radio channel to station A. The packets generated by the respective data transmission protocol DÜP may be composed of a variable number of frames, for example, where the number of frames per packet may be between 1 and 15, for example, depending on the quality of the wireless link. Each frame may in turn consist of a 5 byte header of control information, followed by a data part between 4 and 250 bytes long, for example, and a redundancy code (CRC) 2 bytes long, for example. Through the choice of the data volume per frame and the choice of the number of frames per packet, the packet length of the data transmission protocol DÜP can be selected as desired, e.g., between 64 bytes and 8 kbytes, in each station A and B at the transmitting end.

Of the incoming data packets in radio drivers RA and RB from the higher-level data transmission protocol DÜPHE, the number, length, priority and type (control information, data information, acknowledgments, etc.) are determined, and depending on these characteristics, the data transmission protocol DÜP with which the data packets to be transmitted are divided into individual data packets before being transmitted over the transmitter of station A is adjusted accordingly. For example, if a number of short data packets of 100 bytes, for example, to be transmitted is detected in radio driver RA, then the length of data packets generated according to the data transmission protocol DÜP is set at this length. If a plurality of long packets of several kilobytes, for example, arrive at the radio driver, the packets DÜP are lengthened as much as allowed by the data occurrence at the remote station and the instantaneous channel quality.

18-01-2000 EP 009901220

CLAIMS

1. Method of transmitting data over a bidirectional radio channel, where digital data to be transmitted is divided into individual data packets according to a first data transmission protocol (DÜPHE), then at the two transmitting and receiving stations of the radio channel, the data is divided according to a second data transmission protocol (DÜP) into individual data packets which are transmitted alternately forward and in reverse over the radio channel by the simplex method,

characterized in that

at each transmitting and receiving station (A or B)

the number

and/or the length

and/or the priority

and/or the type of data packets generated by the first data transmission protocol (DÜPHE) and sent to the respective transmitter of the station is determined as the data packet identifier, and the length of the data packets generated by the second data transmission protocol (DÜP) is determined in at least one of the transmitting and receiving stations as a function of these data packet identifiers in the sense of optimum utilization of radio channel capacity.

2. Method according to Claim 1, characterized in that data packet identifiers are determined at one sending and receiving station (e.g., A), and the data

packet length is determined as a function thereof at the same station.

packets in the second data transmission protocol (DÜP).

3. Method according to Claim 1, characterized in that data packet identifiers determined at one transmitting and receiving station (e.g., A) are transmitted to the remote station (e.g., B) where they are used to influence the length of the data

REVISED PAGE

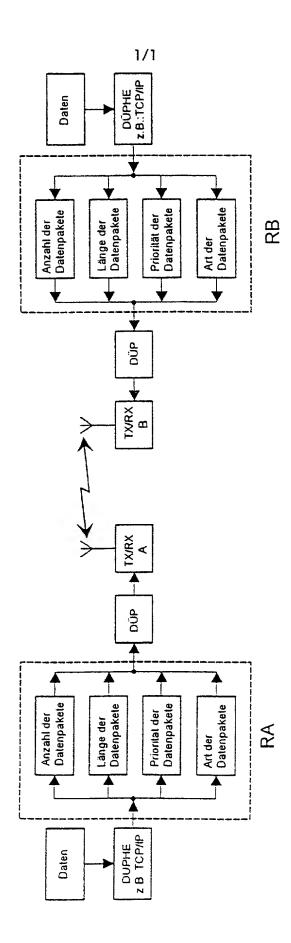

18-01-2000 EP 009901220

4. Method according to one of the preceding claims, characterized in that

the data packet identifiers determined at both transmitting and receiving stations (A and B) are transmitted to the respective remote station, where they are used to set the length of the data packets of the second data transmission protocol (DÜP).
